1 Introduction

Venture capital investors face a complex and intricate task when it comes to assessing and evaluating the potential of a company. Typically, this involves a thorough analysis of the company’s business model, financials, and market competition. However, the availability of vast amounts of data has led to the emergence of new techniques, such as natural language processing (NLP), which can process and analyze large volumes of unstructured text data with ease.

One such technique is Bidirectional Encoder Representations from Transformers (BERT), which has proven highly effective in various NLP tasks, including text paraphrasing and question answering. In this paper, we propose a method that utilizes BERT to create embeddings of company descriptions and cluster them based on similarity. After dimensionality reduction, we map these embeddings onto a two-dimensional plot, providing a visual representation of the similarities and differences between companies. By clustering and visualizing companies based on their descriptions, investors can identify potential investment opportunities, make informed decisions, and gain insights into the trends and patterns of the startup ecosystem.

Moreover, this technique is not limited to venture capital. It can be applied to other tasks such as market research, competitor analysis, job matching, and analyzing changes in a company’s language to identify its strategic shifts and competitive positioning. Overall, its versatility means that it can be useful in tasks that traditionally involve laborious manual market research and analysis.

The primary aims of this paper are to demonstrate a method for embedding company descriptions using a dataset of 1.27 million companies, discuss the technical details of the BERT model, and justify the effectiveness of the proposed method through experimentation. However, this research topic poses several challenges, including the need for a vast amount of data to train the BERT model accurately and selecting the appropriate clustering and dimensionality reduction algorithms to ensure both efficiency and accuracy. Additionally, the quality of company descriptions and the lack of standardization in language can significantly impact the model’s performance. Despite these difficulties, we believe that the proposed method can provide valuable insights and assist investors in navigating the complex and dynamic landscape of startups and innovation.

2 Data

The dataset used for this project consists of 1.27 million rows of company names, domain names, and company descriptions. An example of the data is listed in Table 1. All data can be requested from Vela Partners.

Name	Domain name	Description
Nordisk	<code>nordisk.eu</code>	Nordisk Company A / S designs, develops and sells products...
Online	<code>online.net</code>	Online is one of the pioneer of the French web hosting industry...
Avybe	<code>avybe.com</code>	Avybe is a new monetization hub for content creators and...
GD Webs	<code>gdwebs.net</code>	GD Webs creates functional and easy-to-use websites that...
⋮	⋮	⋮

Table 1: The first few rows of the dataset.

Preliminary preprocessing of data removes rows with empty entries and removes especially short

descriptions (less than 15 words), such as:

- The Todd & Rahul Angel Fund is a venture capital firm.
- Grupo Ganga is a production company that tells stories and creates television.
- Danphil Conseils provides software solutions.

Especially long sentences were also removed. The cutoff for outliers in length is given by $Q_3 + 1.5(Q_3 - Q_1)$, where Q_1 and Q_3 are the lower and upper quartiles, respectively. Since the cutoff turned out to be 138.5, sentences longer than 140 words were removed.

Finally, non-English entries were detected using the `langdetect` package [1] and removed.

Due to time and space limitations, the preprocessed data was then sampled randomly down to a 100k dataset (99413). Though the model was trained on both the full and sampled dataset, the version trained on the full dataset is not thoroughly tested, and the resulting file was approximately 8 gigabytes and difficult to put into production.

3 Methodology

3.1 Overview

To automatically classify companies based on their descriptions, we propose a modular pipeline consisting of several unsupervised learning submodels. The overall architecture of the pipeline is illustrated in Figure 1, along with popular models for each task. In this section, we provide an in-depth discussion of the various submodels employed in the pipeline.

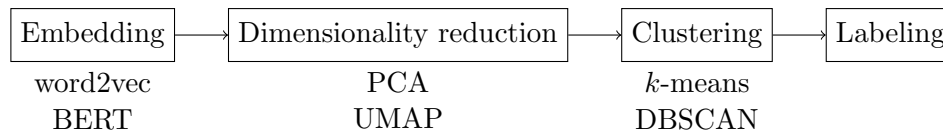

Figure 1: Pipelining of the model.

The first step involves creating embeddings for company descriptions. This process involves mapping each description to a vector, which enables the representation of natural language text in a quantitative format using a series of numbers. This vector representation enables comparison between descriptions using distance metrics such as cosine similarity.

Next, the objective of the clustering step is to identify descriptions that are similar to each other and group them into distinct clusters. Popular clustering algorithms include k -means and DBSCAN (density-based spatial clustering of applications with noise). However, these algorithms can suffer from the curse of dimensionality, where the performance degrades as the dimensionality of the input data increases [2]. Since text embeddings can have several hundred dimensions, we employ dimensionality reduction techniques like PCA (principle component analysis) and UMAP (uniform manifold approximation and projection) to enable effective clustering.

Finally, once the clusters of company descriptions are formed, for ease of access and intuitive understanding, the descriptions of each cluster are to be summarized into a label for a cluster. There are many generative models available for this task – this paper proposes a novel approach in Section 3.5.

Once the clusters of company descriptions are formed, we generate a label for each cluster by summarizing the descriptions within the cluster. In the context of business and financial applications, human interpretability is crucial as it helps build an intuitive understanding of the clusters and facilitates informed investment decisions. Several generative models can be used for this task, and we propose a novel approach in Section 3.5.

The modular nature of our approach allows for submodels to be updated and improved as more efficient or accurate versions and iterations become available. Additionally, the modularity enables hyperparameter tuning for each submodel and data to be saved between each step, avoiding the need for repeatedly retraining the entire model.

We note that the recent BERTopic model has a significant overlap with our pipeline, as it performs document embeddings, dimensionality reduction, and clustering [3]. However, we found the topic representation extracted by BERTopic not to be human-friendly and intuitive enough for our specific application of topic modeling. Therefore, we leverage BERTopic for the first three steps in our model as it provides an encapsulated package for the pipeline, and we use the results to separately generate more user-accessible cluster labels.

3.2 Sentence-BERT

Liren Song proposed the use of word2vec for analyzing unstructured text data in a previous study with this dataset [4]. However, BERT, a pre-trained neural network model that encodes input sequences bidirectionally, has been shown to be a more effective model in interpreting text in context [5]. For instance, a company description might contain the phrase “diversified portfolio comprised primarily of bank loans,” while another might include “sells screen protectors, cases, audio equipment, power banks.” The word “bank” has two different meanings, and BERT, unlike word2vec, generates two distinct embeddings for each meaning.

Nevertheless, BERT is a word-level model, and using linear combinations of word embeddings for sentence embeddings often produces suboptimal results in tasks such as clustering. To address this limitation, Sentence-BERT (S-BERT) was used, which is a variation of the BERT model that has been specifically designed for sentence-level tasks. The mechanisms behind BERT and S-BERT make them both effective at learning contextualized representations of text, which is crucial for many NLP tasks [6]. However, S-BERT’s specifically designed sentence-level representations, learned using a siamese architecture and triplet loss function, enable it to capture the meaning of sentences in a more robust manner than BERT, making it a strong choice for tasks that require a deep understanding of the semantic meaning of sentences [7].

Specifically in the S-BERT framework, we employed `all-MiniLM-L6-v2`, a general-purpose pre-trained model that has demonstrated excellent performance across a wide range of use-cases. The model was trained on a diverse dataset of over one billion sentence pairs and is significantly faster and smaller in size than comparable models [8].

With S-BERT, stopwords were not removed from the text as context is necessary for its interpretation.

3.3 UMAP

The BERTopic documentation proposes the use of UMAP or PCA as a faster alternative for dimensionality reduction. UMAP (uniform manifold approximation and projection) has gained popularity

since it was published in 2018 due to its ability to preserve both global and local structures in high-dimensional data and its effectiveness in capturing nonlinear relationships between features. PCA (principle component analysis), on the other hand, is a linear technique that only preserves global structure.

Since, in natural language processing tasks, the data is high-dimensional and nonlinear in nature, we chose to use UMAP as it preserves the relationships between words and phrases in nonlinear text data much better. This enables better clustering in the following steps.

Figures 2 and 3 from Pinecone [9] show a comparison between PCA and UMAP when applied to the dataset of the geographical locations of major cities in the world. As the three-dimensional data is reduced into two dimensions, PCA applies a linear transformation and "squishes" the points onto a plane along the axis that preserves the most variance. In contrast, UMAP preserves the structure by maintaining the relative distances between cities. For example, the gap between the light blue points that represent Africa is the Sahara desert, where there are no major cities. Another example is how Southeast Asian islands are separated from the rest of Asia.

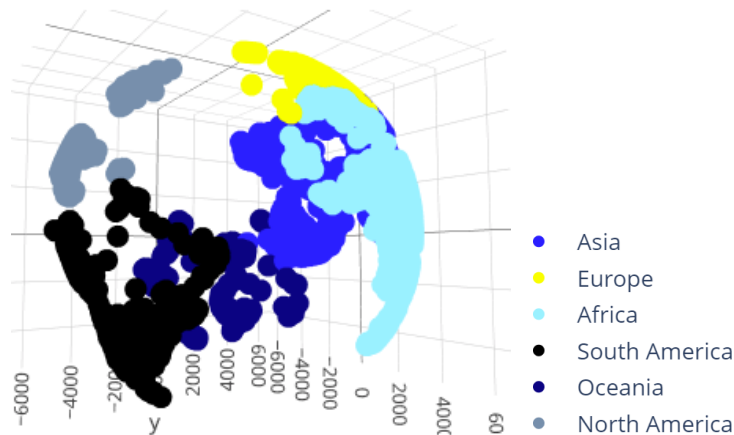

Figure 2: Original data in three dimensions.

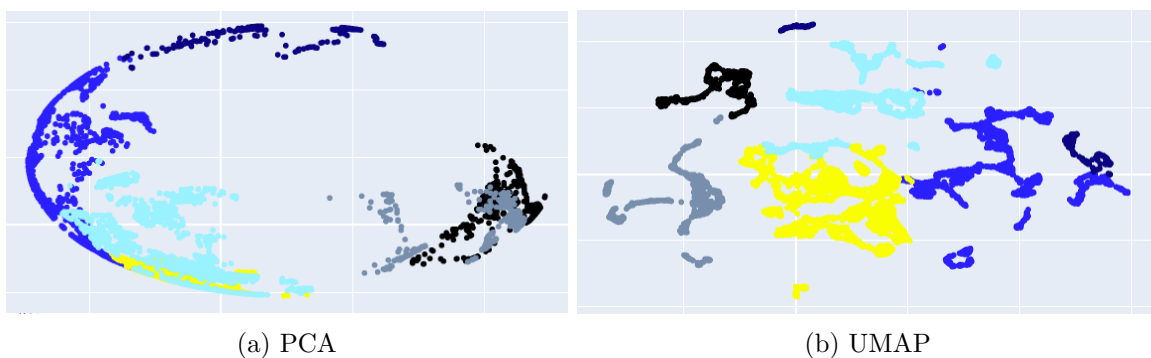

Figure 3: The data in two dimensions, after applying each dimensionality reduction method.

We see that UMAP is better at dealing with real-world, unstructured data.

3.4 HDBSCAN

Both the BERTopic and UMAP documentations recommend HDBSCAN for clustering. A faster, more elementary approach is k -means, so we test its validity in this use-case. k -means is a popular clustering algorithm used to partition a dataset into k clusters, based on the similarity of the data points to each other. The algorithm works by iteratively assigning data points to the nearest cluster centroid and updating the centroid until convergence.

The elbow method is used in k -means clustering to find the optimal number of clusters by plotting the within-cluster sum of squared distances (WCSS) against different values of k . The elbow point is the point of inflection where the WCSS starts to decrease at a slower rate, indicating the optimal number of clusters. If there is no clear elbow point, it may indicate that the data has no clear clustering structure, or that k -means is not suitable for the data.

After reducing the dimensionality of the data, the elbow plot in Figure 4 was obtained after attempting to cluster the data.

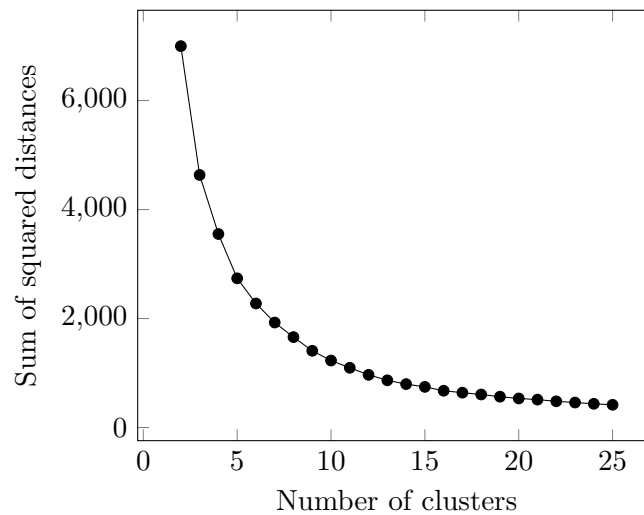

Figure 4: Elbow plot of k -means clustering

Note that there is no elbow in the plot between $k = 2$ and $k = 25$. Although there may be one for $k > 25$ that could imply an optimal cluster number, k -means is ineffective for a large number of clusters, so we turn to HDBSCAN.

HDBSCAN is a hierarchical density-based clustering algorithm that identifies clusters of varying densities and shapes in data. It uses a parameter-free approach to automatically determine the number of clusters and can handle noise and outliers effectively [10]. HDBSCAN is an effective model for NLP clustering tasks because it can identify meaningful patterns in text data that are not apparent using traditional distance-based clustering algorithms, due to the high-dimensionality and sparsity of text data. Additionally, HDBSCAN's ability to handle variable density and shape of clusters is beneficial for NLP tasks where the data may exhibit complex structure and non-uniform, non-spherical distribution [11].

3.4.1 Outliers

A feature of HDBSCAN is that it classifies outliers – data that do not fit in any of the clusters it finds – into a separate pile with label `-1`. On one hand, HDBSCAN’s ability to handle outliers means that it can still cluster data effectively even if there are some data points that do not fit well into any cluster. For example, when fed the input “The quick brown fox jumps over the lazy brown dog,” a piece of text that is unlikely a company description, the model labeled it as an outlier. This can result in a more accurate clustering of the rest of the data.

On the other hand, since the data for text classification is sparse, a large percentage of training data were classified as outliers. For the 1.2 million dataset, more than 700,000 descriptions (55.6%) were classified as outliers, and for the 100k dataset, approximately 50,000 (50.3%) were classified as so. This suggests that the model classifies many meaningful inputs as outliers.

The current approach involves assigning the second most likely label to a given input if the model classifies it as an outlier. This approach implies that, in the case of a truly meaningless input, it still attempts to classify it with one of the meaningful labels. The potential for improving this method is explored in Section 5.

3.4.2 Cluster size

An important hyperparameter in the HDBSCAN model is `min_cluster_size`, the minimum cluster size, as it directly affects the number of clusters and the relevancy of each cluster. For example, if the minimum cluster size is set to be too low, the model may classify all companies with the word “pinnacle” in its name. If the minimum cluster size is too big, the model creates vague and broad clusters, defeating the purpose of finding underlying structures between company descriptions.

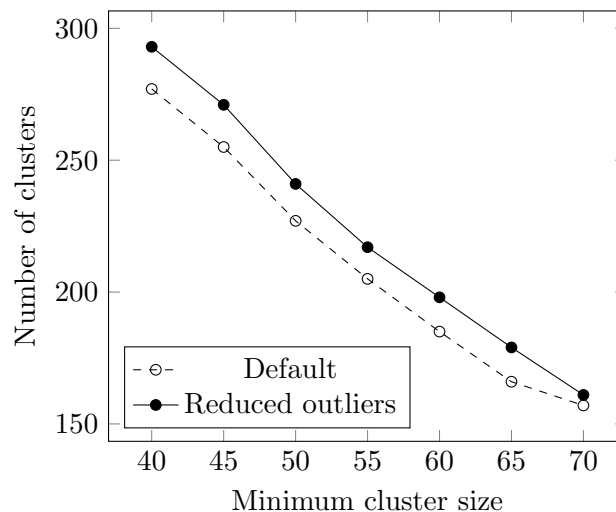

Figure 5: The number of clusters resulting from each minimum cluster size.

Note that HDBSCAN has another hyperparameter, `min_samples`, which measures how conservative the clustering is [12]. The higher the value, the more conservative the clustering and the less likely noise will be classified into a cluster. Since `min_samples` is set equal to `min_cluster_size` by default, to reduce the number of outliers, we allow more noise to be classified into clusters by setting `min_samples` to $\lfloor 0.85 \cdot \text{min_cluster_size} \rfloor$. More fine-tuning can be done, but we find that this strikes a good balance between reducing the number of outliers and retaining the coherence of

clusters.

To find the optimal `min_cluster_size`, in Figure 5, we plot it against the number of clusters in which it results. The Industry Classification Benchmark (ICB) [13] classifies markets into 173 subsectors. For redundancy, we choose to set `min_cluster_size` at 60, which results in 197 clusters.

3.5 Label generation

To summarize the companies in each cluster, we propose using prompt engineering with GPT-3 to generate human-readable category names. We utilized the OpenAI API to input a prompt, along with the three most representative descriptions from each cluster. After testing various prompts, we found that the following prompt yielded promising results:

```
'I will give you three company descriptions that belong in the same industry.
Please come up with a name for the category in which all companies belong,
and be specific with the name while staying concise. Say nothing but the name
of the category; do not add the word "Category" in front of your response.'
```

We selected the `text-davinci-003` model for its speed and accuracy, and we used a temperature of 0.4 since a summarization task requires not too much variance and creativity.

The resulting category names, along with an example company from each cluster, can be found in the Appendix. This approach provides a simple yet effective method for summarizing clusters of companies, making it easier for humans to interpret and understand the data.

4 Results

Given that the proposed model is based on an unsupervised learning framework, no straightforward metric for quantitatively evaluating its performance is readily available. Additionally, due to time constraints, it was unfeasible to manually label the data to benchmark the model's results. Future research could explore assessing the model by employing topic coherence metrics [14] and inter-topic diversity metrics [15] to provide a more comprehensive evaluation.

Nevertheless, this study showcases sample outputs produced by the model when provided with inputs from company descriptions within the 1.2 million dataset but not the 100k subset. This offers a qualitative glimpse into the model's clustering behavior and the practicality of the generated categories.

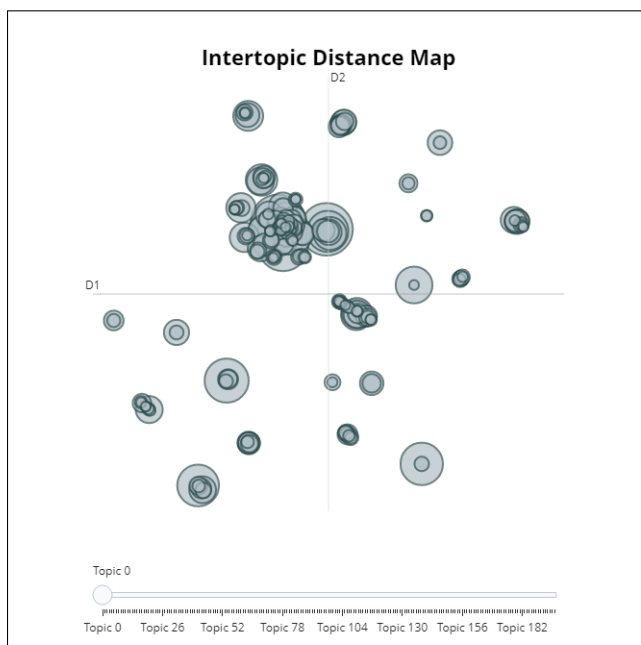

In order to facilitate the model's usage, the following API functions were implemented:

- A visualization function that returns a two-dimensional representation of the clusters. Similar clusters are situated closely, and dissimilar clusters are positioned further apart in the representation.
- A classification function that accepts a company description as its input, and returns a category to which it belongs along with a confidence score.
- A lookup function that takes a cluster as its input and retrieves all companies belonging to that cluster from the 100k dataset.
- A keyword search function that searches for a cluster given a keyword.

The following subsections demonstrate sample outputs of each API function.

4.1 Visualization

```

         'Digital Marketing Agencies'])
```

5 Future studies

While the results presented above are promising, there are several areas for future improvement and expansion.

5.1 Preprocessing

To enhance the performance of the model, we recommend the following preprocessing improvements.

1. **Removal of generic words.** The model could benefit from eliminating generic words such as "company," "offer," and "service" from the descriptions. These words may not contribute much to the content and can cause the model to create a cluster with descriptions that use these words often.
2. **Better filtering of short sentences.** Tying into the idea of removing generic words, the current processing of filtering out short sentences of less than 15 words may fail to remove sentences that are long but lack content. For example, the description "Rise.Life offers you the opportunity to grow your own outstanding activities company, and make a real difference in your community" is 21 words long, but lack information on what the company's operations are. Removing generic words may improve the filtering.

3. **Removal of company names from descriptions.** Including company names in their descriptions may lead to incorrect clustering based on superficial features. For instance, Topic 65 mainly consists of companies with a capital Q in their name, (e.g. Quantflo, Qoderoom, Qualbe Marketing Group, and Spin Quantum Tech). Though many companies operate businesses related to quantum technology, these features do not necessarily indicate a similarity in business scope.

5.2 BERT fine-tuning

Fine-tuning a BERT model involves adapting a pre-trained BERT model to better understand and generate sentence embeddings for a specific domain or task. This can enhance the model’s performance in dealing with domain-specific vocabulary, acronyms, and jargon, which are often prevalent in company descriptions. By training the model on domain-specific vocabulary, it can more accurately capture the true meaning and nuances of the descriptions [16].

5.3 Other modifications

1. **Decreasing prompt length to GPT-3.** To lower API call costs, future studies could explore reducing the prompt length while maintaining the quality of the generated responses. This can be done by summarizing the prompt and removing unnecessary words.
2. **Outlier reduction** The model’s performance could be further improved by reducing the number of outliers. One approach to achieve this is to compute the c-TF-IDF representations of outlier documents and assign them to the best matching c-TF-IDF representations of non-outlier topics. This strategy can help create more coherent and meaningful clusters. More strategies are discussed in BERTopic’s documentation [17].

6 Conclusion

In conclusion, this paper has presented a novel approach to utilizing BERT for embedding company descriptions and clustering them based on similarity, offering valuable insights to venture capital investors and other stakeholders. By leveraging the power of BERT, we have demonstrated a practical and efficient method to visualize the relationships between companies in a startup ecosystem, providing a valuable tool for decision-making and market analysis. Although challenges such as text quality and data inconsistencies may impact the model’s performance, the proposed method has shown promising results in aiding the understanding of industry trends and patterns. As the field of NLP continues to evolve, it is anticipated that these challenges will be addressed, allowing for further improvement and refinement of this technique. Ultimately, this research contributes to the broader application of NLP in market research, competitor analysis, job matching, and strategic shifts identification, showcasing its potential to transform the way we approach and understand complex data-driven environments.
